This report describes the results of a major data gathering effort carried out in the spring and summer of 2004 aimed at tracking deployment of Intelligent Transportation Systems (ITS) technology in metropolitan areas in the United States. Metropolitan ITS is defined in terms of nine infrastructure components: Freeway Management, Incident Management, Arterial Management, Electronic Toll Collection, Electronic Fare Payment, Transit Management, Highway-Rail Intersections, Emergency Management, and Regional Multimodal Traveler Information. Deployment is tracked through the use of indicators tied to the major functions of each component. In addition, integration of components is tracked, the measure being based on a comparison of the reported extent of the transfer of information between components to the maximum possible. The report summarizes results at a national level and includes information on the number of metropolitan areas deploying selected technologies related to the indicators. Two separate metropolitan surveys are included in this report: a survey of 78 major metropolitan areas, and one of 30 medium-sized metropolitan areas.
Preface

This report presents an update of a major nationwide data gathering effort tracking the deployment of the metropolitan Intelligent Transportation Systems (ITS) technology in metropolitan areas in the United States. This report documents results of a survey conducted in 2004. This survey was conducted in two parts, one covering 78 major metropolitan areas and the other 30 medium sized metropolitan areas, was an update to an on-going survey effort, last carried out in 2002. Tracking the deployment of ITS infrastructure is an important element of ITS program assessment, as implementation of ITS technology is an indirect measure of effectiveness of the ITS program. Information regarding deployment activities provides feedback on progress of the program that can help stakeholders establish strategies for continued market growth. Understanding the rate of ITS deployment in various metropolitan areas can lead to insights regarding future program changes, redefinition of goals, or maintenance of current program direction.

The methodology followed to complete this effort is based on the development of deployment indicators designed to capture the most important functions provided by a particular ITS infrastructure component. The nine components tracked include: Freeway Management, Incident Management, Arterial Management, Transit Management, Electronic Fare Payment, Electronic Toll Collection, Highway-Rail Intersections, Emergency Management, and Regional Multimodal Traveler Information. In addition, indicators were developed to capture the level of integration of these components.

Questions or comments concerning the material presented in this report are encouraged and can be directed to:

Executive Summary

In January 1996, former Secretary Peña set a goal of deploying the integrated metropolitan Intelligent Transportation System (ITS) infrastructure in 751 of the nation's largest metropolitan areas by 2005:

"I'm setting a national goal: to build an intelligent transportation infrastructure across the United States to save time and lives, and improve the quality of life for Americans. I believe that what we do, we must measure . . . Let us set a very tangible target that will focus our attention . . . I want 75 of our largest metropolitan areas outfitted with a complete intelligent transportation infrastructure in 10 years."²

-- Former Secretary Peña, 1996

In order to track progress toward fulfillment of the former Secretary's goal for deployment, the United States Department of Transportation (USDOT) Intelligent Transportation Systems (ITS) Joint Program Office (JPO) developed the metropolitan ITS deployment tracking methodology in 1997. This methodology tracks deployment of the nine components that make up the ITS infrastructure: Freeway Management; Incident Management; Arterial Management; Emergency Management; Transit Management; Electronic Toll Collection; Electronic Fare Payment; Highway-Rail Intersections; and Regional Multimodal Traveler Information. Information is gathered through a set of surveys distributed to the state and local agencies involved with these infrastructure components. The surveys gather information on the extent of deployment of the infrastructure and on the extent of integration between the agencies that operate the infrastructure. Deployment is measured using a set of indicators tied to the major functions of each component. Integration is measured by assessing the extent to which agencies share information and cooperate in operations based on a set of defined links between the infrastructure components. The details of the methodology are explained in a separate report.³

In FY97, the ITS JPO undertook a baseline survey of deployment in 78 of the nation's largest metropolitan areas following the metropolitan ITS deployment tracking methodology and published the results in a series of site reports and a nationwide summary report. During the summer and fall of 1999, the ITS JPO undertook a new data collection effort for the purpose of updating the 1997 survey results. This process was repeated in 2000, 2002, and 2004. In 2002, the scope of the national survey was expanded to include additional metropolitan areas and to track deployments in rural areas. A total of three national surveys were conducted in 2004. The first was an update of the 78 metropolitan areas that had been surveyed previously. The second was an update to the survey of 30 additional metropolitan areas, smaller in population than the original 78 and reporting

¹ Since former Secretary Peña's speech, the number of metropolitan areas that DOT will measure has been increased from 75 to 78. However, to maintain reporting consistency across the 10-year goal period, this report considers only the original 75 metropolitan areas.
² Excerpt of a speech delivered by former Secretary of Transportation Peña at the Transportation Research Board in Washington, DC on January 10, 1996.
relatively high levels of congestion. These areas are called ‘medium-sized cities’ throughout this report. The third survey targeted each of the 50 states and gathered data on statewide and rural deployments. This report is a national summary of the FY2004 results for the two metropolitan surveys. The statewide results will be reported separately\(^4\). This report is a summary of a large amount of data. For those interested in additional details, access to the complete data set, including results from previous surveys, is available on-line at: http://www.itsdeployment.its.dot.gov/.

**Summary Deployment Indicators for Large Metropolitan Areas**

As will be seen in Section 2 of this report, the level of deployment of each of the ITS infrastructure components is described by a number of indicators. These indicators have been chosen to serve as estimators of the extent of technology deployment supporting critical functions. For each component, one of these indicators has been designated to serve as a summary for the whole component, allowing national results to be portrayed in a single graph. Figure 1 presents the 78 largest metropolitan areas summary indicators. The FY2004 results are compared to results from 1997, 1999, 2000, and 2002. In addition, responders were asked to estimate deployment levels in the year 2005 as part of the 2004 survey and these projections are included in the figure. The indicators developed for deployment tracking are surrogates that do not necessarily reflect the full breadth of deployment. Because deployment goals have not been established at the metropolitan area level, these indicators should not be read as a comparison of what is deployed versus eventual deployment goals. Instead, these indicators only reflect what is deployed in each metropolitan area compared to full market saturation (i.e., the full deployment opportunity).

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

![Figure 1 78 Large Metropolitan Areas Summary Indicators](attachment:image.png)
Integration Indicators for Large Metropolitan Areas

ITS integration is measured using 34 links that have been defined within the ITS infrastructure. These links are both inter-component (e.g., the sharing of arterial and freeway traffic condition information between freeway and arterial management agencies) and intra-component (e.g., the sharing of traffic signal timing information between arterial management agencies). The measure of integration is the simple calculation of the number of agencies that participate in integration compared to the total number of agencies that possibly could. As with the deployment indicators, this measure does not make a distinction between those agencies that should be linked and those that should not. Figure 2 presents the national summary of integration results for the FY2004 survey.

Figure 2 78 Large Metropolitan Areas Integration Links
**How to Read This Figure**

Figure 2 portrays the national summary indicators for integration. Indicators were developed to measure the level of integration between infrastructure components using a set of defined links (both inter- and intra-component).

A total of 34 individual integration links were specified. Each integration link has been assigned a number and an origin/destination path from one ITS infrastructure component to another. Both inter- and intra-agency links are considered.

For example, the number “11” identifies the integration of information from the Freeway Management component to the Arterial Management component. Each link represents the real-time sharing of information flowing in a particular direction. In the example, freeway management agencies within a metropolitan area share information gathered on traffic conditions with arterial management agencies to improve coordination of traffic control.

Another type of integration link defines the integration of agencies in the same infrastructure component. In this example, at least one arterial management agency in a metropolitan area shares information on signal timing with another to support regionally coordinated signal control. The extent of integration is reported in the diagram for each link through the level of shading in the circle.

The measurement of integration associated with each of the links is agency-based. The calculation is simple and is an expression of the number of agencies that share data divided by the total number of agencies that possibly could. Therefore, for each of the integration links, a percentage integration score, ranging from zero to one hundred, is assigned. The circle is shaded accordingly to reflect this percentage. As with the deployment indicators, this rating system is based on the maximum possible integration without consideration of whether it is needed in every case.
Measuring Progress in Integrated Deployment

Deployment tracking data were used to develop a methodology for developing and tracking goals for integrated deployment to support monitoring of progress toward the former Secretary's 10-year goal. Deployment is measured using a set of threshold values for the major infrastructure components. A metropolitan area is assigned a rating of low, medium, or high based on the number of thresholds attained. Integration is measured by evaluating the existence of integration links between a subset of the infrastructure--freeway management, arterial management, and transit management. An integration rating of low, medium, and high is assigned and combined with the deployment rating to produce a single overall rating for integrated deployment. Crossing a threshold value for either deployment or integration means that a metropolitan area has made a significant commitment to deploy and integrate the metropolitan ITS infrastructure. However, it does not mean that deployment or integration is complete. The 10-year goal will be met if all of the 75 metropolitan areas are rated medium or high for integrated deployment. This methodology is explained in detail in section 4. Figure 3 summarizes the level of deployment in 75 of the nation's largest metropolitan areas for 1997, 1999, 2000, 2002, and 2004. A detailed description of the methodology and results for each metropolitan area is available in a separate report5.

![Figure 3 Progress in Integrated Metropolitan ITS Deployment](image-url)

---

Summary Deployment Indicators for Medium-Sized Cities

The summary indicators for the medium-sized cities surveyed are presented in Figure 4. Compared to the same indicators shown in Figure 1, arterial, transit, and emergency management agencies in medium-sized cities have deployed ITS similarly to those in major metropolitan areas. However, freeway deployment in medium-sized cities, in the form of traffic data collection and service patrols, is substantially lower than in the larger cities.

**Medium-Sized Cities**

**Summary Indicators***

- Freeway miles with real-time traffic data collection technologies
  - 2002: 3%
  - 2004: 8%
  - 2005: 23%

- Freeway miles covered by on-call service patrols
  - 2002: 19%
  - 2004: 27%
  - 2005: 35%

- Arterial miles covered by on-call service patrols
  - 2002: 7%
  - 2004: 9%
  - 2005: 10%

- Signalized intersections under centralized or closed loop control
  - 2002: 43%
  - 2004: 49%
  - 2005: 55%

- Toll collection lanes with Electronic Toll Collection capability
  - No Response

- Fixed-route transit vehicles equipped with Automatic Vehicle Location
  - 2002: 27%
  - 2004: 41%
  - 2005: 49%

- Fixed-route buses accepting electronic fare payment
  - 2002: 76%
  - 2004: 81%
  - 2005: 80%

- Highway-rail intersections under electronic surveillance
  - 2002: 1%
  - 2004: 6%
  - 2005: 9%

- Emergency management vehicles under Computer-Aided Dispatch
  - 2002: 26%
  - 2004: 81%
  - 2005: 80%

- Freeway conditions disseminated to the public

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Figure 4 Medium-Sized Cities Summary Indicators
Introduction

Background

This report describes the state of Intelligent Transportation System deployment in the nation’s metropolitan areas. The data presented are based on the results of a nationwide survey conducted in 2004 using the tracking methodology developed by the United States Department of Transportation’s ITS Joint Program Office. This methodology tracks deployment of nine components that make up the metropolitan ITS infrastructure: Freeway Management; Incident Management; Arterial Management; Emergency Management; Transit Management; Electronic Toll Collection; Electronic Fare Payment; Highway-Rail Intersections; and Regional Multimodal Traveler Information. Through a set of indicators tied to the major functions of each component, the level of deployment is measured for the nation's largest metropolitan areas. In addition, the integration links among agencies operating the infrastructure are also tracked. The details of the methodology are explained in a separate report.  

In FY97, the ITS JPO undertook a baseline survey of deployment in 78 of the nation's largest metropolitan areas following the metropolitan ITS deployment tracking methodology and published the results in a series of site reports and a nationwide summary report. During the summer and fall of 1999, the ITS JPO undertook a new data collection effort for the purpose of updating the 1997 survey results. This process was repeated in 2000, 2002 and 2004. In 2002, the scope of the national survey was expanded to include additional metropolitan areas and to track deployments in rural areas. A total of three national surveys were conducted in 2004. The first was an update of the 78 metropolitan areas that had been surveyed previously. The second was an update to the survey of 30 additional metropolitan areas, smaller in population than the original 78 and reporting relatively high levels of congestion. The third survey targeted each of the 50 states and gathered data on statewide and rural deployments. Overall, the 2004 data gathering involved 2300 agencies with a 94% response rate.

This report is a national summary of the FY2004 results for the two metropolitan surveys. Where possible, 2004 data are reported along with earlier data to show deployment trends. The statewide results are summarized in a separate report. For those interested in additional details, access to the complete data set, including results from previous surveys, is available on-line at: http://www.itsdeployment.its.dot.gov/.

The first section of this report covers the results for the survey of the country’s 78 largest metropolitan areas. Initially, these results are described through a set of summary indicators for deployment and integration that provide a high level view of the overall results, followed by a detailed breakout of individual deployment indicators for each infrastructure component. Trend information from earlier surveys is also included. Integration is also be covered in detail, and instead of individual components, the results are grouped according to major functions: traffic

---

6 Additional Resources: "Measuring ITS Deployment and Integration"
management, traveler information, transit, and emergency management. Following these results, the 2004 results for the 30 medium-sized cities are presented.

National Summary Indicators for 78 of the Nation’s Largest Metropolitan Areas

Several deployment indicators have been developed for each component. However, a single indicator has been selected for the purpose of summarizing the level of deployment for a particular component. The summary indicators are expressed as a percentage; however, because deployment goals have yet to be established, these indicators should not be read as a comparison of what is deployed versus eventual deployment goals. Instead, they only reflect what is deployed compared to full market saturation (i.e., opportunity for deployment). Further, it must be kept in mind that the indicators are surrogates that do not necessarily reflect the full breadth of metropolitan ITS deployment. Figure 5 includes the summary indicators developed from the 1997, 1999, 2000, 2002, and 2004 survey results. The 2004 survey asked respondents to estimate 2005 levels of deployment, and this projection of deployment indicators is also presented in this figure. The information presented in this figure suggests the following:

- Summary deployment indicators have increased across all components during the period 1997 to 2004 with one exception: Highway-Rail Intersections, which as remained fairly static.
- The highest levels of deployment are observed for Emergency Management (computer aided dispatch), and Electronic Toll Collection, which are approaching complete deployment.
- The deployment of Incident Management on arterials lags significantly behind that reported for freeways, but has shown a steady rate of increase for the period of the surveys. The rate of growth in the deployment of incident management slowed somewhat in 2004.
- Transit agencies are deploying technology on a significant portion of their fleets, with a major increase projected for 2005.
- The deployment of centralized or closed loop control of traffic signals appears to be reaching a steady state at about 50% of traffic signals.
- Freeway deployment, in the form of traffic surveillance and service patrols, has been increasing steadily and projections indicate this trend will continue in the future.
**Figure 5 78 Large Metropolitan Areas Summary Indicators**

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.
Figure 6 portrays the metropolitan national summary indicators for integration. See page 5 for an explanation of this figure.

The results show that information dissemination varies widely among the links between different infrastructure components, but that some components, such as incident and emergency management, are fairly well integrated. Information dissemination to the public is also generally well established. A disturbing finding is the low levels of integration between transit, arterial and freeway agencies. The fact that this low level of integration in no way reflects the generally high level of deployment of ITS technology by the individual agencies indicates the cause may be institutional rather than technical.

![78 Large Metropolitan Areas Integration Links Diagram]
Infrastructure Component Description and Survey Results for Major Metropolitan Areas

This section presents deployment-tracking indicators for each of the nine metropolitan ITS components for the 78 major metropolitan areas. The following information is provided for each component:

1. A description of the basic functions performed by each component.

2. Data gathering results for each indicator displayed in a set of graphs. The horizontal bar graph that portrays results is expressed as a percent of deployment opportunity achieved for each indicator. The deployment opportunity reflects the total potential deployment and does not necessarily reflect actual need. For example, freeway management indicators are compared to a deployment opportunity consisting of the entire freeway system and are not corrected for any assessment of how local conditions might limit the scope of deployment to a portion of the freeway system. These indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity. Where possible, FY2004 results are compared to FY1997, 1999, 2000, and 2002 results and estimates for FY2005. In some cases, a decrease in deployment or integration over time occurs. This reduction may be due to agencies responding one year and not the other, or an actual decrease in the level of deployment.

3. Additional survey results are used to evaluate the extent that individual metropolitan areas have adopted technologies. This information is displayed in graphs that show the number of metropolitan areas reporting the presence of a particular technology that supports a component. In many cases, metropolitan areas have more than one of these technologies. As with the indicators, FY2004 results are compared to FY1997, 1999, 2000, and 2002 results, and 2005 estimates.
**Freeway Management**

Freeway Management provides the following traffic management functions:

1. Surveillance: Capability to monitor traffic conditions on the freeway system in real-time
2. Control: Capability to implement appropriate traffic control and management strategies (such as ramp metering and lane control) in response to recurring or non-recurring flow impediments.
3. Information dissemination. Capability to provide critical information to travelers through infrastructure-based dissemination methods such as Variable Message Signs (VMS), Highway Advisory Radio (HAR), or In-Vehicle Signing (IVS).

The Freeway Management component indicators are shown in Figure 7. Traffic surveillance has shown steady growth since 1997, a trend that is projected to continue to 2005. Traveler information systems are also projected to increase through 2005, with the rate of growth for variable message signs exceeding that for highway advisory radio. On the other hand, deployment of traffic control systems, either through ramp metering or lane control is virtually static.

---

**Figure 7 Freeway Management in the Largest 78 Metropolitan Areas**

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

**Deployment opportunity reflects potential totals that do not necessarily reflect actual need.*
Traffic Surveillance

Figure 8 contains the number of metropolitan areas that use various surveillance technologies. The most frequently used electronic surveillance technology is loop detectors, but adoption by new metropolitan areas is limited. On the other hand, although radar detectors and video image detectors are less widely deployed, both technologies show substantial growth, a trend that is projected to continue in the future.

![Figure 8 Surveillance Technologies](chart)
Traffic Control

Traffic condition data are analyzed to identify the cause of a flow impediment and to formulate an appropriate response in real-time. Traffic control devices, such as ramp meters or lane control devices, may be applied to provide a better balance between freeway travel demand and capacity during congested conditions.

Figure 9 shows the number of metropolitan areas that use lane control or ramp metering, the type of ramp meter control used, and the number of metropolitan areas that have ramp meter preemption for emergency vehicles and priority for transit vehicles. The deployment of ITS technology to control traffic on freeways, in the form of either ramp metering or lane control, is not expanding at the same rate as the surveillance and information dissemination functions of freeway management. Although the use of lane control has recently expanded, ramp metering has been basically static.

Figure 9 Traffic Control Devices
Information Display

Information may be provided to travelers through roadside traveler information devices such as VMS, HAR, and IVS.

Figure 10 contains a summary of the number of metropolitan areas reporting the use of information display technologies. The most frequently used technology is VMS, followed by HAR. The use of both technologies has shown steady growth. No metropolitan area reports using IVS.

![Figure 10 Information Dissemination](image-url)
**Incident Management**

Incident Management provides the following traffic management functions in real-time:

1. Incident detection. Capability to detect incidents on freeways and arterial roadways.
2. Incident verification. Capability to verify incidents on freeways and arterial roadways.
3. Incident response. Capability to respond to incidents on freeways and arterial roadways.

The Freeway and Arterial Incident Management component indicators are shown in Figure 11. The use of free cellular phone call numbers is the primary means of detection of incidents. There has been steady, rapid growth in the deployment of closed circuit television to assist in incident verification. Growth in the coverage of freeway on-call service patrols to respond to incidents is slowing and may be approaching a steady state of about 50% coverage. Arterial incident management is expanding, but remains much less prevalent than incident management on freeways.

![Figure 11 Freeway and Arterial Incident Management in the Largest 78 Metropolitan Areas](image-url)---

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

**Deployment opportunity reflects potential totals that do not necessarily reflect actual need.*
**Incident Detection**

Monitoring of freeway conditions for the purpose of incident management is usually integrated with Freeway Management, with notification of the presence of an incident provided to the Incident Management component.

Figure 12 shows the number of metropolitan areas that use various incident detection methods. Use of free cellular phone calls to a dedicated number is about as common as the use of incident detection algorithms. These technologies are deployed on both freeways and arterials with a significant expansion for both categories reported in 2004 and even greater growth projected for 2005.
Incident Verification

Incident verification is typically accomplished through observation by closed circuit television cameras. Figure 13 shows the number of metropolitan areas that use surveillance cameras for incident verification on arterials and freeways. This technology is widely deployed.

![Figure 13 Incident Verification](image)

Incident Response

Roadways are cleared and flow restored as rapidly as possible, minimizing frustration and delay to travelers while at the same time meeting the requirements and responsibilities of the agencies involved.

Figure 14 shows the number of metropolitan areas that use various incident response methods in freeways. More than half of the metropolitan areas reporting use publicly operated service patrols. The growth in new deployments has slowed and is projected to decrease in 2005.
Figure 15 shows the number of metropolitan areas reporting the use of publicly operated service patrols for incident response on arterials. Although the coverage of these service patrols is limited, as was shown above in Figure 11, nearly half of the metropolitan areas report some level of deployment.
Arterial Management

Arterial Management provides for the following traffic management functions:

1. Capability to monitor traffic flow conditions on arterials in real-time (i.e., traffic surveillance).
2. Capability to implement traffic signal timing patterns that are responsive to traffic flow conditions (i.e., traffic control).
3. Capability to provide critical information to travelers through infrastructure-based dissemination methods such as VMS, HAR, or IVS (i.e., information display).

The Arterial Management component indicators are shown in Figure 16. The deployment of surveillance at signalized intersections has shown rapid growth and is projected to cover over one-third of these intersections by 2005. The use of centralized traffic signals is well established and is projected to include more than half of all signals by 2005; however the rate of growth is slowing and deployment may be approaching a steady state at about 50% of signals. Traveler information systems are still only lightly deployed on arterials.

Figure 16 Arterial Management in the Largest 78 Metropolitan Areas
Traffic Surveillance

Traffic signal control may incorporate peripheral elements that are not essential to the task of traffic control per se, but which may enhance overall traffic management capabilities in an area. These elements could include closed circuit television (CCTV) surveillance, motorist information and/or traveler information components, a database management system to support analysis and development of management strategies, and data exchange with other traffic management systems including freeway management and incident management.

Figure 17 shows the number of metropolitan areas that use electronic surveillance on arterials. This technology is widely deployed and almost all of the major metropolitan areas report having some level of deployment.

Traffic Control

Arterial Management is responsible for the coordinated control of traffic signals along urban arterials, networks, and the central business district. Arterial Management provides the capability to adjust the amount of green time for each street and coordinate operation between each signal in response to changes in demand patterns. Traffic signal timing patterns may be executed in response to pre-established "time of day" or "special event" plans, based on historical traffic conditions, or may be executed in response to real-time traffic conditions using "traffic-adaptive" algorithms. Coordination can be implemented through a number of techniques, including time-based and hard-wired interconnection methods. Coordination of traffic signals across agencies requires development of data sharing and traffic signal control agreements. Therefore, a critical institutional component of Arterial Management is the establishment of formal or informal arrangements to share traffic control information as well as actual control of traffic signal operation across jurisdictions.
Figure 18 contains a summary of metropolitan areas that use various control technologies. All of the metropolitan areas that have responded report signalized arterial intersections under centralized or closed loop control. The deployment of signals with emergency preemption is also widely deployed, and is reported by more than twice as many metropolitan areas as deploy signal priority for transit.

Figure 18 Traffic Control
**Information Display**

Information may be provided to travelers on arterials through roadside traveler information devices such as VMS and HAR.

Figure 19 contains a summary of metropolitan areas that use various display technologies on arterials. Nearly half of the large metropolitan areas employ variable message signs and/or highway advisory radio. While variable message signs had the early lead in deployment, highway advisory radio is catching up.

![Figure 19 Information Dissemination](image_url)
Electronic Toll Collection

Electronic Toll Collection (ETC) provides for the following traffic management function:

1. Electronically collect tolls. Automatically collect toll revenue through the application of in-vehicle, roadside, and communication technologies to process toll payment transactions.

The Electronic Toll Collection component indicators are shown in Figure 20. This technology is so widely reported that its deployment is essentially complete.

---

**Figure 20** Electronic Toll Collection in the 78 Largest Metropolitan Areas

---

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

**Deployment opportunity reflects potential totals that do not necessarily reflect actual need.
Figure 21 contains the number of metropolitan areas that have toll collection lanes with ETC capability. The deployment of this technology has not increased very much over time, reflecting the limited number of metropolitan areas collecting tolls.

![Figure 21 Lanes with ETC Capability](image)
Electronic Fare Payment

Electronic Fare Payment (EFP) provides for the following fare payment functions:

The Electronic Fare Payment component indicators are shown in Figure 22. This technology has shown steady growth in adoption on fixed-route buses, with the coverage more than doubling since the start of the survey in 1997. Nearly two-thirds of the buses have this capability in 2004.

Figure 22 Electronic Fare Payment in the Largest 78 Metropolitan Areas

- Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
- Deployment opportunity reflects potential totals that do not necessarily reflect actual need.
Figure 23 contains the number of metropolitan areas that use electronic fare payment media for fixed-route bus services. Magnetic stripe cards are the most widely accepted media. The number of metropolitan areas using smart cards doubled in 2004 and this rapid rate of growth is projected to continue in 2005.

Figure 23 Fixed Route Vehicles Accepting EFP

Figure 24 shows the number of metropolitan areas that use electronic fare payment for heavy-rail stations. This type of deployment showed substantial growth in 2004, and this is projected to continue through 2005.

Figure 24 Rail Stations Accepting EFP
Transit Management

Transit Management provides for the following functions:

1. Capability to monitor the location of transit vehicles to support schedule management and emergency response (i.e., Automatic Vehicle Location [AVL]).
2. Capability to monitor maintenance status of the transit vehicle fleet.
3. Capability to provide demand responsive flexible routing and scheduling of transit vehicles.
4. Capability to provide real-time, accurate transit information to travelers.

The Transit Management component indicators are shown in Figure 25. The use of automatic vehicle location systems is well established and is reported in nearly half of the transit vehicles. Computer aided dispatch is similarly well established in the management of paratransit vehicles. The use of electronic monitoring of transit vehicles showed a large increase in 2004.

---

**Figure 25 Areas Transit Management in the Largest 78 Metropolitan Areas**

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.*

**Deployment opportunity reflects potential totals that do not necessarily reflect actual need.**

---

Percent Deployment Opportunity**

- Fixed-route transit vehicles equipped with Automatic Vehicle Location
- Fixed-route transit vehicles with electronic monitoring of vehicle components
- Paratransit vehicles that operate under Computer-Aided Dispatch
- Major transfer points with electronic display of information (1997 only)
- Bus stops with electronic display of information (1997 only)

---

*Percentages reflect deployment opportunity in the largest 78 metropolitan areas.*

---

Table showing deployment percentages for different transit management components.
Automatic Vehicle Location

Transit Management supports management of the transit fleet by electronically monitoring vehicle locations in real-time. Transit vehicles equipped with AVL technology provide the basis for vehicle tracking. Information on the current location of a transit vehicle is transmitted to a centralized dispatcher who then compares the actual location with the scheduled location. Depending on the variance between the actual and scheduled locations, actions may be taken to improve schedule adherence and to transfer information to travelers. This technology also supports emergency response by providing real-time information on vehicle locations in emergency situations.

Vehicle Maintenance Monitoring

Transit Management includes electronic monitoring of vehicle performance parameters using in-vehicle sensors. This involves monitoring of usage statistics such as mileage and status of routine scheduled maintenance. In addition, this permits automatic monitoring of vehicle conditions including key parameters such as oil and fuels levels and tire pressure.

Paratransit Vehicle Dispatching

The use of AVL also supports advanced demand-responsive computer-aided routing and scheduling. Transit dispatchers can combine real-time information on vehicle location and status with advanced Computer Aided Dispatching (CAD) systems to provide optimal vehicle assignment and routing to meet non-recurring public transportation demand.

Figure 26 shows the number of metropolitan areas reporting the use of AVL on fixed-route services, the use of electronic vehicle maintenance monitoring systems, and the use of a CAD system for demand-responsive vehicle dispatching. All are well established and show strong growth in the 2004 results.
**Highway-Rail Intersection**

Highway-Rail Intersection provides for the following function:

Electronically monitor Highway-Rail Intersections to: (a) coordinate rail movements with the traffic control signal systems, (b) provide travelers with advanced warning of crossing closures, and (c) improve and automate warnings at highway-rail intersections.

The Highway-Rail Intersection component indicator is shown in Figure 27. Deployment of this technology is basically static.

![Percent Deployment Opportunity](image)

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

**Electronic Surveillance**

The at-grade highway-rail intersection is a special form of roadway intersection where a roadway and one or more railroad tracks intersect. At a Highway-Rail Intersection, the right-of-way is shared between railroad vehicles and roadway vehicles, with railroad vehicles typically being given reference. Railroad trains, which travel at high speeds and can take up to a mile or more to stop, pose special challenges. As a result, automated systems are now becoming available that allow the deployment of safety systems to adequately warn drivers of crossing hazards.

The Highway-Rail Intersection component involves electronic surveillance of grade crossings to detect vehicles within the crossing area, either through video or other means such as loop detectors. These systems may eventually support real-time information on train position and estimated time of arrival at a crossing and interactive coordination between roadway traffic control centers and train control centers.

Figure 28 contains the number of metropolitan areas reporting the use of electronic surveillance at highway rail intersections, which is reported by nearly half of the major metropolitan areas, as well as intrusion detection devices.
Figure 28 HRI Surveillance
Emergency Management

Emergency Management provides the following capabilities:

1. Vehicle dispatch. Capability to operate public sector emergency vehicles under CAD.
2. Route guidance. Capability to provide public sector emergency vehicles with in-vehicle route guidance capability.

The Emergency Management component indicators are shown in Figure 29. The use of computer aided dispatch is widespread and is reported in three fourths of the emergency vehicles. Deployment of in-vehicle navigation systems is expanding rapidly and more than doubled in 2004.

### 78 Largest Metropolitan Areas

**Emergency Management***

*Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity. **Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

**Percent Deployment Opportunity**

*Figure 29 Emergency Management in the Largest 78 Metropolitan Areas*

**Computer-Aided Dispatch**

Emergency vehicle fleet management utilizes AVL equipment to provide CAD of vehicles. Through the use of real-time information on vehicle location and status, emergency service dispatchers can make optimal assignment of vehicles to incidents.

**Route Guidance**

The installation of route guidance equipment in emergency service vehicles provides improved directional information for drivers and improves responsiveness of emergency services.
Figure 30 contains the number of metropolitan areas with emergency management vehicles under computer aided dispatch and route guidance technologies. Computer aided dispatch is universally reported. In-vehicle route guidance is expanding rapidly to new metropolitan areas and is widely adopted.

![Figure 30 EMS Vehicles Technologies](image)
Regional Multimodal Traveler Information

Regional Multimodal Traveler Information provides for the following capabilities:

1. Collection of data. Collect current, comprehensive, and accurate roadway and transit performance data for the metropolitan area.
2. Data dissemination. Provide traveler information to the public via a range of communication techniques (broadcast radio, FM subcarrier, the Internet, cable TV) for presentation on a range of devices (home/office computers, television, pagers, personal digital assistants, kiosks, radio) (i.e., media).
3. Multimodal support. Provide multimodal information to the traveler to support mode decision-making.

The Regional Multimodal Traveler Information component indicators are shown in Figure 31. Traveler information capability covered nearly one third of freeway miles in 2004. The use of a variety of media to disseminate information is growing steadily. Traveler information is becoming multi-modal, with nearly one-half of the traveler information systems incorporating two or more modes.

### Figure 31 Regional Multimodal Traveler Information in the Largest 78 Metropolitan Areas

- **Freeway conditions disseminated to the public**:%
- **RMTI media type used to display information**:%
- **RMTI media type used on two or more modes**:%

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.
**Freeway Conditions Disseminated to the Public**

The Regional Multimodal Traveler Information component of the metropolitan ITS infrastructure involves information dissemination by a number of agencies. The indicator tracks the percentage of freeway miles in each metropolitan area for which data are gathered through surveillance systems and traffic information made available to the public.

**Media Employed to Disseminate Traveler Information**

Agencies or organizations use many methods to disseminate traveler information to the public. Indicator calculations are based on a deployment opportunity of eight media: dedicated cable TV, telephone systems, web sites, pagers, interactive TV, kiosks, e-mail, and in-vehicle navigation. The indicator assigns a percentage for each metropolitan area based on the number of these eight media employed to distribute traveler information.

**Media Displaying Information on More Than One Transportation Mode**

Traveler information on more than one transportation mode may be displayed on a single medium. For example: Transit schedules and fares as well as freeway travel times, speeds, or conditions may be displayed on a Web site. This indicator tracks the percentage of the eight possible media for which information on more than one mode is disseminated.
Integration in Large Metropolitan Areas

A critical aspect of the deployment of ITS technology that provides much of its capability is the integration of individual components to form a unified regional traffic control system. Individual ITS components routinely collect information that is used for purposes internal to that component. For example, the Arterial Management component monitors arterial conditions to revise signal timing and to convey these conditions to travelers through such technologies as VMS and HAR. Agencies operating other ITS components can make use of this information in formulating control strategies. For example, Transit Management agencies may alter routes and schedules based on real-time information on arterial traffic conditions, and Freeway Management agencies may alter ramp metering or diversion recommendations based on the same information.

Figure 32 portrays the national summary indicators for integration. See page 5 for an explanation of this figure.

In order to make the discussion of individual links clearer, links have been grouped into four broad categories: (1) Traffic Management Integration, (2) Traveler Information Integration, (3) Transit Management Integration, and (4) Emergency Management Integration. The integration rating is indicated by the shading in the circles associated with each link in Figures 33 to 36.
**Traffic Management Integration**

Traffic Management Integration enables the implementation of coordinated traffic management strategies among operating agencies responsible for Freeway Management, Incident Management, and Arterial Management within a metropolitan area. Key characteristics of Traffic Management Integration include the following:

1. Collection of real-time traffic and incident data on the freeway and arterial street network.
2. Coordination of management actions in response to changes in traffic flow.
3. Collaboration among operating agencies to optimize the strategies available to improve traffic flow.

Figure 33 presents an overview of the integration links that define Traffic Management Integration. Freeway management and incident management are well integrated. Other interagency integration is more limited, however. In particular, integration between freeway, arterial, and transit management is quite limited.

![Figure 33 Traffic Management Integration Links](image-url)

</tbody>
</table>
Traveler Information Integration

The collection, processing, and distribution of timely information related to the performance of the transportation system is a by-product of integrating selected metropolitan ITS components. Information gathered by Freeway Management, Incident Management, Arterial Management, and Transit Management components is fused to create a region-wide traveler information database. Information in the database is then transferred to various media for display to travelers. Travelers receiving this information can make better-informed decisions regarding if, when, where, and how to travel, which may lead to an increase in travel efficiency and a reduction in travel congestion and delay. Figure 34 presents an overview of the integration links that define Traveler Information Integration. Arterial management information is only rarely made available to travelers. On the other hand, transit information, particularly schedule information, is widely available. Information on incidents is also widely disseminated.

Summary Deployment Indicators for Medium-Sized Cities

The summary indicators for the medium-sized cities surveyed are presented in Figure 37. The highest rate of deployment is for Emergency Management, followed by Transit Management, and Arterial Management. Surveillance on freeways is lightly deployed in medium-sized cities, but is expanding rapidly, with substantial growth projected. Incident Management on-call service patrols covered more than one quarter of the freeway miles in medium sized cities in 2004 and are projected to cover more than one-third by 2005.

![Medium-Sized Cities Summary Indicators](image)

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Figure 37 Medium-Sized Cities Summary Indicators
**Freeway Management**

Figure 38 summarizes the level of Freeway Management in the medium-sized cities surveyed. The results indicate that only a limited level of freeway deployment is present in these areas. The most widely deployed technology is Highway Advisory Radio, followed by Variable Message Signs.

57
Incident Management

Figure 39 summarizes the level of incident management in the medium-sized cities surveyed. Freeway Survey Patrols are deployed on nearly 20% of the freeway miles in these areas. Arterial incident management is lightly deployed in these areas, a result that is similar to that observed in the larger areas. The deployment of ITS on freeways in general is projected to increase markedly by 2005 in the medium-sized cities.

Medium-Sized Cities

Freeway and Arterial Incident Management*

- Freeway miles under incident detection algorithms
- Freeway miles under free cell phone call to a dedicated number
- Freeway miles covered by surveillance cameras
- Freeway miles covered by on-call service patrols
- Arterial miles under incident detection algorithms
- Arterial miles under free cell phone call to a dedicated number
- Arterial miles covered by surveillance cameras
- Arterial miles covered by on-call service patrols

Percent Deployment Opportunity**

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Figure 39 Medium-Sized Cities Freeway and Arterial Incident Management Indicators
**Arterial Management**

Figure 40 indicates that Arterial Management is widely deployed in the medium-sized cities surveyed. A significant proportion of traffic signals are under centralized or closed loop control and a high proportion of intersections are covered by electronic surveillance.

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Figure 40 Medium-Sized Cities Arterial Management Indicators
**Transit Management**

Figure 41 summarizes the level of Transit Management in the medium-sized areas. 2004 results show rapid growth. Nearly one-half of the paratransit vehicles operate under Computer-Aided Dispatch. Almost one half of the vehicles are equipped with Automatic Vehicle Location as well. There is a large increase in deployment of ITS for transit projected for 2005 in medium sized cities.

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Highway-Rail Intersections

As presented in Figure 43, very few highway-rail intersections are under electronic surveillance in the medium-sized cities surveyed.

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.
** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Figure 43 Medium-Sized Cities Highway-Rail Intersections Indicators
Emergency Management

Figure 44 shows that a large proportion of emergency management vehicles are equipped with Computer Aided Dispatch in the medium-sized areas. The use of in-vehicle navigation units is expanding rapidly.

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.
Regional Multimodal Traveler Information

Figure 45 summarizes the level of Regional Multimodal Traveler Information in medium-sized areas surveyed. The results show that traveler information is expanding rapidly in medium-sized cities.

![Medium-Sized Cities Regional Multimodal Traveler Information Indicators](image)

- Freeway conditions disseminated to the public: 1% in 2002, 6% in 2004, and 9% in 2005.
- RMTI media type used to display information: 44% in 2002, 54% in 2004, and 61% in 2005.
- RMTI media type used on two or more modes: 19% in 2002, 27% in 2004, and 29% in 2005.

* Indicators are single surrogates that do not necessarily reflect the full breadth of ITS deployment activity.

** Deployment opportunity reflects potential totals that do not necessarily reflect actual need.

Integration Indicators for Medium-Sized Cities

Figure 47 summarizes the level of integration in the medium-sized areas surveyed. The highest levels of integration appear between Incident Management and Emergency Management. The results are comparable to those seen for the major metropolitan areas, including the poor integration between transit, arterial, and freeway agencies.

Figure 47 Medium-Sized Cities Integration Indicators
Comparison of Medium-Sized and Major Metropolitan areas

Overall, how do these results compare to those for major metropolitan areas? Table 5 shows a comparison of the deployment summary indicators for the 78 major metropolitan areas and the 30 medium-sized areas for 2004. These results show that agencies involved with emergency management, arterial management, and transit in medium-sized cities deploy similarly to those in larger cities. There is a marked difference, however, in the level of deployment of technologies on freeways. This is clear for both electronic surveillance as well as service patrols on freeways.

Conclusions

The 2004 survey results indicate that the adoption and deployment of key ITS technologies continue to advance in major cities. Deployment of freeway surveillance and closed circuit television cameras is advancing rapidly. The use of technology to support transit, public safety, arterial traffic management, and toll collection is also advancing apace. However, this good news is balanced by the lack of integration between key metropolitan agencies, which is the continuation of a long standing and disturbing trend. These results indicate that ITS technology is being deployed to improve efficiency and effectiveness of individual agencies, with less emphasis on using the real-time data and flexible control capabilities from ITS to create a regionally integrated transportation management system. The addition of medium cites to the survey makes it possible to draw additional conclusions. One of these conclusions is that deployment on freeways is closely tied to city size, with a marked difference shown between large and medium-sized metropolitan areas. The second conclusion is that with the exception of freeway management, agencies generally deploy similarly, regardless of the size of the metropolitan area in which they are located.
